PROFESSIONAL SUMMARY

Computer Science undergraduate (B.Tech, 2027) who builds production backend and AI systems and then reviews them adversarially. Authored the security and governance layer of AegisProxy, an LLM gateway: constant-time credential comparison, a ten-pattern PII and PAN redactor with Luhn validation, an atomic Redis rate limiter, per-tenant budget caps and a circuit breaker — then published a findings register documenting the prompt-injection surfaces, information-disclosure paths and incomplete redaction rules still present in that same codebase. Earned a Special Mention in Caterpillar's hackathon recruitment for Cat FleetIQ, a fleet control tower with 65 REST endpoints and a rules-plus-anomaly detection engine. Seeking Software Development Engineer roles.

EDUCATION

Jain University, Bengaluru — B.Tech, Computer Science and Engineering 2023 – 2027

TECHNICAL SKILLS

Security Engineering: Secure Code Review, Threat Modeling, Timing-Attack Mitigation (constant-time comparison), PII and PAN Redaction (DLP) with Luhn Validation, Prompt-Injection Surface Analysis, SQL Injection Prevention, Header Injection, Insecure Deserialization, Trust Boundary Analysis, Fail-Safe Defaults, Least-Privilege Gates, Rate Limiting (Redis Lua token bucket), Circuit Breakers, Anomaly Detection (Isolation Forest), Findings Reporting with Severity Classification

Languages: Java, Python, C, JavaScript, TypeScript, SQL, Lua

AI / Machine Learning: Scikit-learn, TensorFlow, NumPy, Pandas, KMeans, PCA, Isolation Forest, Random Forest, Gradient Boosting, Support Vector Machines, TF-IDF, Natural Language Processing, SHAP and LIME (Explainable AI), Linear Programming (PuLP)

LLM Engineering: LiteLLM, Model Context Protocol (MCP), OpenAI and Google Gemini APIs, Semantic Caching, Vector Search (FAISS), Sentence Transformers, Context Compression, Prompt Engineering

Backend, Data and DevOps: FastAPI, REST API Design, async SQLAlchemy, WebSockets, Redis, SQLite, Pydantic, GraphQL, API Gateway Design, React, Next.js, Tailwind CSS, Hadoop, Hive, ETL Pipelines, Star-Schema Warehousing, Docker, Docker Compose, Git, GitHub Actions (CI/CD), pytest, Linux

Core Computer Science: Data Structures and Algorithms, Object-Oriented Programming, Operating Systems, Computer Networks, DBMS

PROJECTS

AegisProxy — LLM Gateway with Security and Governance Layer | *GitHub*

Tech: Python 3.11, FastAPI, LiteLLM, Redis, Lua, FAISS, Sentence Transformers, SQLite, Docker, pytest, GitHub Actions

- Authored the authentication layer: constant-time API key comparison via *compare_digest*, defeating byte-by-byte key recovery through a timing side channel, with separate read and write authorization gates so the observability surface — which carries prompt text — locks down automatically once an admin key signals the deployment is exposed.
- Built a ten-pattern PII and PAN redactor ordered most-specific-first so an email is consumed before bare digit patterns can fragment it, with a Luhn checksum keeping order IDs out of the card bucket, per-type hit counts surfaced to operators, and redaction enabled by default so raw prompts are never persisted without an explicit opt-out.
- Enforced abuse controls at the gateway chokepoint: an atomic Redis Lua token bucket closing the check-and-decrement race that separate GET and SET would leave open, per-tenant budget caps, a three-state circuit breaker filtering dead providers before the call, correlation IDs bounded at 128 characters against header injection, and closed-set Prometheus labels so a hostile prompt cannot explode metric cardinality.
- Published a findings register against my own codebase with exploitability, blast radius and remediation per item: verbatim provider errors that can echo prompt content, an unfenced transcript in the summariser as a live prompt-injection surface, and a PRIVATE_KEY pattern matching only the header line that leaves the key body exposed.
- Routed 100+ LLM providers behind an OpenAI-compatible API via LiteLLM, cutting repeat-query latency from a 500ms–2s upstream round trip to under 30ms with a FAISS and Redis semantic cache over all-MiniLM-L6-v2 embeddings above 0.92 cosine similarity; 389 passing tests, ruff linting and GitHub Actions CI.

Cat FleetIQ — Rental Fleet Control Tower | *Caterpillar Hackathon, Special Mention* · *GitHub*

Tech: Next.js 16, React 19, TypeScript, FastAPI, async SQLAlchemy 2.0, WebSockets, Scikit-learn, PuLP, Docker

- Delivered 65 REST endpoints across 12 routers over a 15-table async SQLAlchemy database, with Pydantic response models bounding every payload so undeclared fields cannot leak, parameterized ORM queries throughout, an explicit CORS origin allow-list, and one shared WebSocket channel pushing live updates to every panel without polling.
- Built a two-layer detection engine — an explainable rule baseline with an Isolation Forest catching what the rules miss, each alert carrying the reason it fired — alongside Holt's linear-trend forecasting with confidence bands and a PuLP solver redeploying idle equipment against forecast shortages, across nine ML and optimization modules.
- Implemented the notification service on real SMTP (smtplib with STARTTLS) with delivery logging, message preview and dry-run mode, so alerts reach live inboxes rather than a stub. Team project, placing directly after the runner-up.

TruthLens — Hybrid Fact-Verification and Fake-News Detection System | *GitHub*

Tech: Python, FastAPI, React, Vite, Scikit-learn, TF-IDF, NLTK, LIME, Google Gemini API, JWT

- Built a three-way hybrid engine fusing a Scikit-learn classifier, a rule engine scoring clickbait triggers, all-caps ratio and punctuation spikes, and a Gemini live web-verification layer over Google Search Grounding, combined by a confidence-weighted ensemble.
- Trained on 53,847 labeled articles to 90.64% accuracy over a 10-stage NLTK pipeline, adding writing-style features beyond TF-IDF — capitalization ratio, sentence length, punctuation and URL counts — to catch signals a bag-of-words model misses.
- Returned a LIME token-level explanation and cited sources with every verdict so no classification is unauditable; served over FastAPI behind JWT auth with a React dashboard.

ACHIEVEMENTS AND TECHNICAL WRITING

- Audited my own IPL match-prediction model and found target leakage — one feature mathematically identical to the label for every row — inflating held-out accuracy from a true 54.4% to 96.3%; removed it from the serving path and hard-blocked it by name against accidental reintroduction.
- Authored a severity-rated change report for AegisProxy v2.0.0 — brief, investigation, findings, remediation, verification, including the hypothesis disproved by reproduction. It surfaced a critical issue outside the brief: all five configured providers silently unreachable with no dashboard signal.
- Authored a complete technical reference for AegisProxy — request pipeline stage by stage, every module, the routing and caching algorithms, and an appendix of known defects graded by severity — plus line-by-line walkthroughs and field manuals for Cat FleetIQ and the IPL pipeline, covering the mathematics behind each module and the reasoning for every model choice over the alternatives rejected.
- Gold Badge in Java on HackerRank; 50-day LeetCode streak; optimized a Java Lomuto-partition QuickSort by removing redundant self-swaps for 8.37% faster runtime.
